ABSTRACT

Introduction: Dyslipidemia is highly prevalent among type 2 diabetic patients. It increases the risk of atherosclerosis and consequent mortality in diabetic patients. The aim of this study was to find out the prevalence of dyslipidemia among type 2 diabetic patients.

Methods: This was a descriptive cross-sectional study in 355 type 2 diabetic patients at tertiary care hospital from 15th May, 2020 to 15th November, 2020 after taking ethical clearance from Institutional Review Committee (Reference no. IRC-PA-052/2077-78). Convenience sampling was done. Demographic and lipid profile variables were recorded based on the structured questionnaires. Data were analyzed by Statistical Package for the Social Sciences version 20. Point estimate at 95% Confidence Interval was calculated along with frequency and percentage for binary data.

Results: Out of total 355 cases of type 2 Diabetes mellitus, prevalence of dyslipidemia was 224 (63.1%). It was more prevalent in male 145 (69.4%) than female 79 (54.1%). Increased Low density Lipoprotein (94.2%) was the most prevalent type followed by mixed dyslipidemia (91.1%).

Conclusions: Dyslipidemia was common among type 2 diabetic patients and was higher in male gender, older age, obesity and longer duration of diabetes. Hence type 2 diabetic patient should undergo the routine monitoring of blood sugar and lipid profile so that any abnormalities can be identified and preventive measures along with interventions can be initiated at the earliest.

Keywords: dyslipidemia; prevalence; T2DM.

INTRODUCTION

Dyslipidemia is one of the major modifiable risk factor for the development of type 2 diabetes mellitus (T2DM), atherosclerosis, stroke and cardiovascular diseases. The occurrence of T2DM exists as the third major non-communicable disease in Nepal. In Nepal, prevalence of dyslipidemia is 63.8% in eastern, 61.0% in central and 90.7% in mid-western region. Dyslipidemia is one of the important risk factor for vascular complications in diabetic patients. It increases free fatty acid flux secondary to insulin resistance and aggravated by increased inflammatory adipokine. T2DM increases the risk of cardiovascular disease (CVD) several fold.

Early detection and proper management of dyslipidemia in diabetic patient helps in prevention of diabetes related complications. Thus, this study aimed to determine the prevalence of dyslipidemia among Nepalese type 2 diabetic population residing in this region.

METHODS

This is a descriptive cross-sectional study conducted at Birat Medical College Teaching Hospital, Nepal from 15th May 2020 to 15th November 2020. A total of 355 patients with Type 2 Diabetes Mellitus (Age >30 years) who attended medicine Out Patient Department were enrolled based on convenience sampling technique.

Prevalence of dyslipidemia was high in patients with high BMI and high LDL was the most prevalent one 173 (93.5%). Prevalence of single and mixed dyslipidemia was higher in patients with longer duration of diabetes (Table 3).

DISCUSSION

The aim of our study was to determine the prevalence of dyslipidemia among type 2 diabetic patients residing in Eastern Nepal. Majority of patients were male, male to female ratio was 1.4:1. Most of the patients were non-vegetarian (85.1%). Similarly more than half of patients were having higher BMI (52.9%) which is shown to be increasing with ageing in our study and is exaggerated by the hyperglycemic state and lipotoxicity; all of these factors can lead to increased risk for atherosclerotic cardiovascular disease.

Dyslipidemia was more prevalent in patients having higher BMI and high LDL, which was the most prevalent 93.5% followed by mixed dyslipidia (91.1%), high total cholesterol (82.1%), hypertglycemia (73.1%) and low HDL (46.9%). High LDL was most prevalent dyslipidemia in both male and female which was 65.1% and 51.4% respectively. These findings are similar to that of reports from Nepal and elsewhere. This is similar to study conducted in Thailand. Changes in lifestyle such as consumption of western style diets which include high calorie foods with increased carbohydrate, fat, and red meat consumption and low fiber diet have contributed to the increased prevalence of obesity, metabolic syndrome and T2DM.

Most common type of dyslipidemia among type 2 diabetes was high LDL was 211 (94.2%) followed by mixed dyslipidemia 204 (91.1%) (Table 2).

There was high prevalence of dyslipidemia in patients with diabetes (63.1%) which is similar to study done by Das et al. However this was slightly lower than other study reported from other part of the country. Our study demonstrated higher prevalence of dyslipidemia among male than female i.e. 69.4% and 54.1% respectively which is comparable to similar study done at tertiary center in this region. When focusing on the subtypes of dyslipidemia, most prevalent was high LDL (94.2%) followed by mixed dyslipidia (91.1%), high total cholesterol (82.1%), hypertglycemia (73.1%) and low HDL (46.9%). High LDL was most prevalent dyslipidemia in both male and female which was 65.1% and 51.4% respectively. These findings are similar to that of reports from Nepal and elsewhere. This is similar to study conducted in Thailand. Changes in lifestyle such as consumption of western style diets which include high calorie foods with increased carbohydrate, fat, and red meat consumption and low fiber diet have contributed to the increased prevalence of obesity, metabolic syndrome and T2DM.

Most common type of dyslipidemia among type 2 diabetes was high LDL was 211 (94.2%) followed by mixed dyslipidemia 204 (91.1%) (Table 2).

from plasma.\textsuperscript{17} Prevalence of dyslipidemia was shown to be more in patient with longer duration of diabetes and most common lipid abnormality was high LDL. This is supported by other study as well.\textsuperscript{18} The exact mechanism by which altered lipid profile is more deranged with disease duration is not very well understood.

This is a small cross-sectional hospital based study representing diabetic patients from the eastern part of Nepal. It did not analyze the effect of lipid lowering treatment in dyslipidemic patients. Glycemic control has not been assessed in this study. The findings of this study, therefore, should be interpreted within context, and may not be generalized to the whole diabetic patients.

**CONCLUSIONS**

Our study showed high prevalence of dyslipidemia among type 2 diabetic patients. Dyslipidemia was higher in male gender, older age, obesity and longer duration of diabetes. These findings should raise awareness regarding prevalence of dyslipidemia among type 2 diabetics to healthcare providers and will help in management of dyslipidemia. Indeed, efforts should be made to increase awareness to public about diabetic dyslipidemia, benefits of change in lifestyle and regular intake of medication and thus decreasing the prevalence of dyslipidemia among diabetic patients.

**ACKNOWLEDGEMENTS**

We would like to express our gratitude to all the participants for participation in this study. We would like to thank department of Biochemistry for evaluation of lipid parameters. We would like to express our sincere thanks to Mrs. Priyanka Pritam, Dr. Amit Kumar Singh and Dr. Suresh Mehta in data interpretation, analysis and wrote up.
